Abstract

Objective: The objective is to recommend the new guidelines to the standard central line associated bloodstream infection (CLABSI) guidelines for use during a pandemic.

Method: Articles from three different databases was conducted: PubMed, Medline, and CINAHL. One hundred articles were retrieved, and seventy-four articles were reviewed and evaluated. The articles were categorized based on the Johns Hopkins hospital/John Hopkins University (2017) hierarchy level of evidence. Four new guidelines were created and added to the ten standard guidelines. Eleven stakeholders rated the recommendations. The stakeholder ratings were sent to a statistician for analysis. The high score ratings are between three and four.

Result: The result of the analysis using Friedman's two-way analysis of variance. Chi-square value X^2 (13) = 7.313, p = .885. The result indicated the differences among the stakeholder's ratings of the fourteen recommendations were insignificant.

Conclusion: Implementation of the recommended guideline will be beneficial during a pandemic.

Keywords: CLABSI, Central Venous Catheter, Pandemic, Guideline.

A CLABSI Guideline for Healthcare Personnel during a Pandemic

A pandemic is an unprecedented outbreak with global repercussions, affecting international, national, and local areas. The World Health Organization [WHO], 2023) confirmed that the number of individuals infected with COVID-19 around the world were: Europe 276,390,270; Western Pacific 203,669,467; Americas 192,775,054; South-East Asia 61,155,081; Eastern Mediterranean 23,374,172; and Africa 9,530,267 (WHO, 2023). Given the high number of confirmed cases of COVID-19, we may assume that a potential next pandemic could have a similar scale. The total number of global infections reached 767,750,853 COVID-19 cases (WHO, 2023). The United States had 99,396,137 infections and continues to see new strains of COVID-19 (Center for Disease Control and Prevention [CDC], 2023).

In the United States COVID-19 infected 146.6 million individuals (CDC, 2022b). Many were hospitalized. Due to the burden of caring for these patients, new staffing models were employed, diverting focus away from routine procedures (Chervoni-Knapp, 2022). As a result, recurring issues such as central line associated bloodstream infection (CLABSI) that may have had low case numbers before the pandemic drastically increased during the pandemic (Alsaffar et al., 2023). The CDC (2022) has reported a significant increase from 2019-2020 in national CLABSI case numbers. It has taken time for many organizations to reduce the numbers of CLABSI back to the levels before the COVID-19 pandemic, an issue that has caused widespread problems in healthcare.

Texas alone had 8,508,204 infected individuals who were diagnosed with COVID-19 infections (CDC, 2023). The situation was further complicated by issues with healthcare staffing (Chervoni-Knapp, 2022). Nurses were observed not adhering to the standard policy for

controlling CLABSIs. Consequently, March and July 2020, one local organization admitted 126,137 patients with COVID-19. The last quarter of 2020 saw a substantial rise in CLABSI rates across the US, with an overall increase of 47%. More specifically, intensive Care Units witnessed a 65% spike, while acute care wards reported a 16% rise in cases (CDC, 2020). The CDC (2023) reported that as of spring 2022, nearly 100 million COVID-19 cases were recorded across U. S., with 1,101,208 related deaths. The state of Texas had reached 8,508,204 cases with 92,378 related deaths. The severity of the pandemic led to an increased casualty rate in acute settings, accompanied by more vascular access complications, thus causing a rise in CLABSIs.

The increased international, national, and local rates of CLABSI during COVID-19 led to hospital administrator and infectious disease officer at local facility confirming an increase of CLABSI. The ongoing pandemic surge resulted in healthcare gap at the local facility that reflected national and international pandemic trends. A solution to resolve the problem before another pandemic led to the project topic of a CLABSI guideline for healthcare personnel during a pandemic.

The CDC (2015) has guidelines for preventing CLABSIs, and healthcare organizations have policies and procedures to guide healthcare workers in their practice. Despite that, CLABSI rates still increased during the pandemic. The incorrect application of guidelines or policies related to vascular assessment procedures contributed to the increased infection rate. Some of these issues were attributable to staffing problems, including the involvement of traveling nurses, and others were due to staff nurses not adhering to the established policy (Haddadin et al., 2022).

The United States has experienced, pandemic situations in the past. Historically, the sixth cholera pandemic (1910-1911) resulted in 800,000 deaths, the influenza pandemic (1918-1920) led to about one million deaths, and the HIV/AIDS pandemic (2005-2012) caused a staggering

death of 36 million (MPH Online Staff, n.d.). In the recent pandemic, worldwide 766,895,075 people were confirmed to have a COVID-19 infection and 6,941,095, people died (World Health Organization [WHO], 2023). These diseases may not have been the sole reason why so many individuals died. Associated complications also play a part.

When evaluating the impact of the COVID-19 pandemic on CLABSI rates, it is important to recognize the rates not associated with pandemic disease. In their study, Baier et al. (2020) discussed the increased rate of CLABSI infections attributed to central venous catheter insertion among hematological and oncological patients undergoing treatment for reasons unrelated to the pandemic. The study involved the insertion of 680 CVC lines in patients with an average age of 47 years. The three different prevalent diseases of the patients were non-Hodgkin lymphoma, acute lymphoblastic leukemia, and hematopoietic stem/cell bone marrow transplantation. The results indicated that 111 cases with a primary nosocomial CLABSI prevalence of 18.2%, which indicated an increased rate of 10.6 CLABSI cases per 1,000 CVC days.

Haroun et al. (2021) detailed a study on the increase in CLABSI cases due to COVID-19 in an 889-bed teaching hospital. The retrospective review study involved evaluating CLABSI cases confirmed through PCR tests for COVID-19. These were compared with CLABSI cases without a COVID-19 diagnosis. The rate of CLABSI cases with COVID-19 was 6.6 times greater than non-Covid CLABSI cases, with the ICU setting having 94% and other units at 53%.

Fakih et al. (2022) reported an increased rate of CLABSI in a retrospective study conducted during the COVID-19 pandemic. The study compared CLABSI rates twelve months before the onset of COVID-19 to six months after its arrival. A marked increase of 51% was observed, with rates rising from 0.56 to 0.85 per 1000 catheter-days. Uncontrolled CLABSI led

to increased mortality rates, extended hospital stays, and elevated healthcare costs (Haddadin et al., 2021).

CLABSIs are known to impact both adults and neonates. Soarez et al. (2018) discussed a retrospective cohort study of infants with a central line placement from July 2014 to June 2016, which conducted at the neonatal intensive care unit (NICU) of Centro Hospital de Sao Joao. A total of 400 central lines were placed in 240 infants. The complications accompanying central line placements were 29.6 cases per 1000 catheter days. The highest incidence value of CLABSI among groups in the study rate was 12.4 cases per 1000 catheter days.

Van Bortel et al. (2016) discussed the Ebola outbreak in Africa, noting that Guinea, Liberia, and Sierra Leone were hardest hit, with a tragic history of over 28,000 cases and 11,000 deaths. The outbreak resulted in the disruption of impacted nations' health systems. During pandemics, the rate of patient admissions to acute care settings typically rises. This can lead to a higher incidence of hospital acquired infections (HAI). Complications from these infections, including vascular access issues, can cause sepsis and patient death, thus contributing to an elevated mortality rate (CDC, 2021).

The literature review underscores the critical need for preparedness by infectious disease control units in the face of unprecedented pandemics. The complications arising from COVID-19 resulted in increased mortality and higher government spending to manage the outbreak (Hyte et al., 2023). During these surges or pandemic periods, it was essential for healthcare organizations to adhere to CDC guidelines strictly. Unfortunately, during these surges, permanent healthcare staff nurses experienced burnout due to the increased patient load, extended working hours, and the psychological impact of the crisis. These factors led to a decrease in the number of staff

members available to work. To resolve the issue, healthcare institutions' management brought in agency staff nurses.

During the ongoing surge, the newly employed agency staff received only brief orientation training. One issue resulting from this change was that the agency staff members' methods for changing central line dressings may have ceased to fully align with the institution's policies and procedures (Almahmoud et al., 2020). Because of the surge, the intensive care units were full due to the critical conditions of the patients. Another factor contributing to increased CLABSI was the related practice of some physicians of inserting central vascular catheters at the bedside. Due to the urgency of the situation, the aseptic technique for vascular insertion was sometimes overlooked. These are some of the factors highlighting the importance of implementing practice guidelines for preventing CLABSI. The significance of practice guidelines lies in assisting healthcare providers and patients in making informed healthcare decisions.

The implementation of guidelines regarding policies and procedures can serve as a valuable tool for reducing CLABSI in acute care settings (OSHA, 2020). Furthermore, several evidence-based literature reviews support the finding that these guidelines significantly reduce CLABSI rates in acute care settings, both during pandemic and non-pandemic periods.

In their research study, Premkumar et al. (2023) used qualitative methods and a quasi-experimental research design to assess the knowledge of 150 frontline COVID-19 critical care unit nurses regarding CLABSI bundle protocols and strategies. The results showed that, before testing, 57% of the CCU nurses had inadequate knowledge regarding CLABSI prevention bundles. However, after receiving hands-on training, post-test compliance among staff nurses increased to 83%.

Orozco-Santana et al. (2023) aimed in their study to reduce the incidence of CLABSI in a Cardiothoracic ICU, and they discussed their findings. Nine CLABSI cases were reported during the fiscal year 2018. Evidence-based interventions were implemented, including rounding, education, auditing, the introduction of a blood culture algorithm, and accountability checks for central line care every seven days. As a result, the incidence of CLABSI dropped from nine cases to one in the fiscal year 2019 - 2020 and increased only slightly to two cases in 2021, even as the number of central line days continued to increase.

The American Society of Anesthesiologists (2020) summarized the findings of randomized controlled trials that compared subclavian and femoral insertion sites. They reported that the femoral site exhibited a higher rate of bacterial colonization compared to the subclavian site. Additionally, the internal jugular site had higher infection rates than the subclavian site.

Implementing CDC guidelines for pandemic situations ahead of a surge can help alleviate the burden and complications associated with unforeseen pandemic outbreaks.

Literature Review

A literature review lays the theoretical groundwork for the research project (Paré & Kitsiou, 2016). A literature review is essential for identifying clinical gaps, establishing research methodologies, and recognizing unresolved problems. The project topic for the study is a CLABSI guideline for healthcare workers during a pandemic. The three literature databases utilized were CINAHL, PUBMED, and MEDLINE. The search terms resulted in the identification of hundred publications, of which 74 articles were closely related and were used for the project. The articles were reviewed considering the following: The aim of the study, sample size, measurement method, results, strengths, and limitations, and the study was rated using the evidence level of hierarchy.

Synthesis of the Literature Articles

Four categories or themes: (a) sterile technique, (b) healthcare staff compliance (c) educational training & skills check off, (d) pandemic preparedness.

Sterile Technique

A sterile field reduces the microbial transmission of infective organisms during a procedure. The first theme of the synthesized article is the maintenance of sterile techniques for procedures. Healthcare personnel must use sterile techniques for the insertion and handling of the central venous catheter and the use of PPE by healthcare personnel (AHRQ, 2018). The sterile technique includes washing hands before and after procedures, wearing PPE, and strictly sterile fieldwork during the procedure.

To synthesize the literature articles for these themes, four of the literature articles was considered. Myatra (2019) in his study discussed improving hand hygiene practices to reduce CLABSI rates using an integral education combination of teaching methods and simulation on hand hygiene before and after Training to assess the nurse's knowledge. In their study, Lee et al. (2018) evaluates four-bundle compliance: hand hygiene, chlorhexidine skin preparation, appropriate central venous site, and maximal sterile barrier precaution. Cohen et al. (2019) use a positive deviance approach and work with the physician to determine steps in practice to maintain a sterile environment and safety in inserting the central venous catheters. Yazici and Bulut (2018) demonstrated the care bundle's efficacy in preventing multiple infections in intensive care units.

In a comparison of the reviewed literature for the first theme, it was found that even though the studies of each of the authors are different, they all have a similar theme in common,

and that was to limit infection with the maintenance of sterile technique during procedure or care of the patient. Myatra (2019) discussed the use of hand hygiene to restrict infection. Cohen et al. (2019) ideas were working with the physician to maintain a sterile environment for safe practice. Lee et al. (2019) evaluates four of the vascular bundles; his study is like Yazici & Bulut (2018), which study the efficacy of care bundles in the intensive care unit.

In contrast, Lee et al. (2019) the study was conducted on 1672 adult patients for over three years. Yazici and Bulut's (2018) study were conducted on intensive care patients in a tertiary hospital. In summary, the theme of both authors was to maintain a sterile field, but the study's steps differed.

Healthcare Staff Compliance

The second theme is healthcare staff compliance. The category for the theme is the Antiseptic use of 2% chlorohexidine wipes for bathing patients with central venous catheter sites to limit infection. The healthcare staff must cleanse the central line catheter sites with chlorhexidine, and the needless connector must be covered with curos by the healthcare staff nurse to limit infection (Gillis et al., 2023).

Healthcare staff must maintain compliance after training or implementing a policy by a tertiary institution's leadership. The reviewed literature: Jusino-Leon et al. (2019) discussed using chlorhexidine gluconate baths to reduce central line-associated bloodstream infections.

Engel et al. (2023) describe a quality improvement project to decrease CLABSI in a non-ICU setting. The aim is to assess the quality improvement of the study. The team implemented 2% chlorohexidine gluconate wipes with central lines for daily bathing for non-ICU patients. The CHG wipes intervention increased from 77% in Jan 2020 to 94% in Feb 2021. Pook et al. (2022) performs the use of chlorhexidine gluconate lock solution (CHGLS) as a locking device for

central line infection prevention. Three thousand seven hundred seventy-eight were participants in the study. Randomized control studies were done test, and control studies were used. The result indicates that 29% of patients with no chlorhexidine locks standard care and 18.7% of patients with control study with chlorhexidine locks. Lin et al. (2017) utilizes a systematic review and meta-analysis to assess the effect of a 2% chlorhexidine bed bath on the risk of central line-associated bloodstream infections.

In contrast, the study by Engel et al. (2023) was conducted in a tertiary 24-bed hospital with the healthcare staff in compliance with the use of wipes. The CHG wipes intervention increased from 77% to 94%. Lin et al. (2017) utilized a systematic review and a meta-analysis method for the result. However, there was a difference in the study's steps. Engel et al. (2023) and Lin et al. (2017) show that staff compliance will minimize infection.

Educational Training and skills check off.

The third theme is the educational Training of healthcare personnel to improve and assist in compliance with guidelines. Healthcare workers require educational training and skills check-off. Healthcare staff must comply with the policy (Aloush et al., 2018).

The reviewed article for the theme includes the following: Chi et al. (2020) assess the knowledge and practices of ICU nurses in China. The study was conducted using a survey grade. Each question, answered correctly, was graded as one. The mean score of the 11 questions was 4.02.43% of nurses reported using maximum barrier protection, 14% reported never using 2% chlorhexidine at the incision site, 40% removed the catheter when no longer necessary, 33% reported routinely changing the catheter even when there was no CLABSI infection. Manzo et al. (2022) illustrate the knowledge and practices for central line infection prevention among Brazilian nurses. A mixed approach study design, a combination of qualitative and quantitative

techniques. Completion of questionnaires to assess knowledge and practices and semi-structured interviews to explore barriers to adherence to CLABSI guidelines. The result indicates that the nurses have moderate knowledge regarding CLABSI prevention practices and need more adequate resources to maintain the bundles. Foka et al. (2021) A systematic review was conducted to study the prevention of central line-associated bloodstream infections through educational intervention in healthcare. The results indicated that with academic interventions, there was a reduction in CLABSI infections.

Acharya et al. (2019) demonstrated hands-on Training for the nurses to determine the Impact of nursing education on CLABSI rates. The study aimed to evaluate the effect of nursing education on CLABSI bundles. Post training, there was a significant decrease of CLABSI 8.6 per 100- catheter days, and hand hygiene opportunities decreased to 33.5%.

To synthesize the article for third theme, it was found that there was a CLABSI reduction with educational Training for healthcare personnel.

Pandemic Effect

The fourth theme is to Plan for adequate isolation rooms, either existing rooms or those that may be adapted in preparation for a pandemic (Sharma et al., 2020). Adequate preparedness: The literature article for the fourth theme. Restrictions of visitors during the pandemic to alleviate the spread of infection (Jaswaney et al., (2023). The impact of COVID-19 on CLABSI causes an increase in hospital-acquired infections (Halverson et al., 2022). The effect of the COVID-19 pandemic on CLABSI: CLABSI rates increases by 51% during the pandemic from 0.56 to 0.85 per 1,000-line days (Fakih et al., 2022).

Synthesizing these articles for theme four: The similarity effect of the study indicates COVID-19 had an impact on increasing infection rate. The difference in these studies is that each

author used a variance factor as a determinant for the impact of COVID-19. The study by Jaswaney et al. (2023) was about restrictions of the visitors. Halverson et al. (2022) involved the infectious organism as a co-factor for the increased CLABSI infection rate.

Literature Review for CLABSI During the Pandemic

Alsaffar et al. (in press) examined the impact of the COVID-19 pandemic on CLABSI case rates in intensive care settings. The researchers conducted a retrospective analysis of CLABSI data collected from adult intensive care units over three years, from 2019 to 2022. The data was collected from the Saudi Health Electronic Surveillance Network, with 1440 CLABSI events collected for the study. The findings show a significant rise in CLABSI rates in 2020-2021, with 2.50 incidents per 1000 central line days, compared to 2.16 in 2019.

Aldawood et al. (2021) discussed the impact of the COVID-19 pandemic on CLABSI rates. The researchers conducted CLABSI surveillance data through the National Healthcare Safety

Network at the adult trauma critical care unit of King Abdulaziz Medical City in Riyadh, Saudi Arabia. The study period it was ranged from April 2020 to October 2020. During the prepandemic period, from October 2019 to March 2020, there were zero reported cases of CLABSI. However, from April 2020 to October 2020, the rate significantly increased to 9.2 per 1000 central line days during the pandemic period.

Literature Review for Post-Pandemic CLABSI Rates

The rates of CLABSI after COVID-19 were not specified in most literature, indicating much research still needs to be done. Freire et al. (2023) noted that the COVID-19 pandemic has been associated with a surge in healthcare-associated infections, leading to increased use of broad-spectrum antibiotics. Therefore, there is a need for a guideline that can be used during a pandemic to prevent CLABSI

Project Question

Does a pandemic-specific practice guideline for prevention of CLABSI during a pandemic found to be useful for healthcare providers?

Objectives

- 1. Provide the PICOTS to the librarian at UTA and ask for articles from three different disciplines (nursing, medicine, biomedicine).
- 2. Read and evaluate the articles.
- 3. Categorize the articles.
- 4. Write follow-up recommendations.
- 5. Grade the recommendations.
- 6. Request that stakeholders rate the recommendations.
- Analyze the descriptive data for article evaluations, recommendation grades, and stakeholder ratings.
- 8. Write a manuscript summarizing the findings.

Framework

The Agency for Healthcare Research (AHRQ) National Quality Measure Clearinghouse (NQMC) Domain Framework (Appendix C) was used by the project lead in the creation of the guideline project. The framework focuses on the rationale for health care delivery and population health measures and includes 1) keeps organizational measures consistent with historical convention; 2) clarifies the purpose and the use of the measure for the developers as well as the users; 3) simplifies the search and retrieval of measure within the NQMC; and 4) accommodates the expanding range of measure over time.

The healthcare delivery was used to assess the current performance status of the organization and all healthcare personnel, which supported the creation of this guideline that can be used in a pandemic. The areas of focus were assessment and prevention using the three subgroups: 1) clinical quality measures, 2) related healthcare delivery measures, and 3) clinical efficiency measures (AHRQ, 2018). The framework supported the current guideline review and evaluation for creating a new guideline that can be used in a pandemic to prevent CLABSI.

The ten interventions from the framework included the following: First, only credential physicians can insert the central line catheters. The subclavian area is preferable to the femoral during the insertion to minimize infection. (AHRQ, 2018). Second, the physician must perform the central line placement aseptically and wear personal protection equipment using barrier precautions (Alfonso et al., 2016). Third, the healthcare staff must perform hand hygiene before putting on a glove and washing hands after removing gloves for a procedure. The healthcare personnel would observe hand-washing steps. Hand hygiene before and after entering the patient's room (Myatra, 2019). Fourth, the nurse must change the central line dressing every seven days, and when it is stained or soiled the procedure must be performed aseptically (Gamvroulli et al., 2020)

Fifth, the lumen of the central venous catheter must be cleansed daily with chlorhexidine wipes to limit infection; the needless connector must be covered with Curos disinfecting caps (Gillis et al., 2023). Sixth, the staff nurse must assess the site of the central venous catheters for any signs of infection at the beginning of the shift. Any infected catheter will be reported to the physician for removal order (Hecht et al., 2020) Seventh, the intravenous tubing should be well labeled with dates and times, and the staff nurse should change the tubing per policy (Van de pol et al., 2023). Eighth, the unit's leaders must observe and check off the regular staff annually for

skill performance. The agency and new staff nurse should go through the proper training as arranged by the leaders at the unit (Aloush et al., 2018). Ninth, during the pandemic, agency staff nurses undergo virtual training to know the policy guidelines of the organization (Achary et al., 2019). In the tenth intervention, the healthcare staff bathed patients with venous catheters with 2% chlorhexidine wipes to minimize infection (Lin et al., 2017).

Four new recommendations with evidence-based research articles were added to the framework to strengthen the interventions in preparedness for the pandemic. The recommendations are as follows—first, prepare for more isolation rooms during a pandemic. Most ICUs do not have isolation rooms or are not designed for airborne isolation infections. In preparation for a pandemic, the infection control manager discussed with the administrative department the estimated number of rooms needed for isolation in preparedness for the pandemic (Sharma et al., 2020).

The second recommendation Is the storage of Personal Protective Equipment (PPE). The last pandemic many healthcare organizations did not have an adequate supply of PPE at the beginning of the pandemic. The supply chain manager is responsible for ensuring adequate PPE and other needed materials for use in the unit and storage of the PPE equipment. The supply chain manager is accountable for giving the supply details of the needed PPE supplies to the chief operation officer. The chief operation officer submits the request to the chief finance officer, who is responsible for ensuring the availability of funds for the purchase (Haegdorens et al., 2022).

The third recommendation is implementing a visiting policy to limit community infection transfer to immunocompromised hospital patients. During the last pandemic, most institutions did not develop restriction policies early, and it resulted in an increased rate of COVID-19 in

healthcare institutions. When the administration of healthcare institutions enforced restrictions, it was later found that the COVID-19 rate decreased because of a decrease in the community's widespread infection (Jaswaney et al., 2022). The fourth recommendation is to cleanse and disinfect surfaces around the patients, such as side rails, overhead tables, doorknobs, and the nursing station surface area, that could be a source of widespread infection. The environmental service department is responsible for cleaning the hospital environment. Supervisors should ensure thorough cleaning of surfaces during the pandemic (Cutts et al., 2021).

Methods

The design of the project was a guideline. The guideline was designed for healthcare personnel operating in acute care during a pandemic. A risk assessment management plan was used for the project guidelines to discover some other recommendations that could be added to the standard guidelines for a pandemic (Appendix B). The development of the project was also supported by a SWOT (Strengths, weaknesses, opportunities, and threats) analysis (Appendix C) that helped in identifying available benefits and risks (Kenton, 2023). A risk assessment management plan expresses all foreseeable potential risks and appropriate action to mitigate the risk. A risk management plan assists in achieving project objectives since it facilitates proactively managing problems (Lima et al., 2021).

Population

The population who would be using the guidelines include healthcare personnel (doctors, residents, nurse practitioners, and nurses) and leadership team members caring for patients during a pandemic. This population would also include traveling nurses caring for patients in acute care settings during a pandemic. The administrative members responsible for maintaining compliance with governmental policies within the healthcare organization, like those set forth by

the Occupational Safety and Health Administration (OSHA), will also be considered in the guideline recommendations. The leadership of each acute care setting comprises the directors and managers of each ICU unit. The administrators and leadership would receive reports and are expected to have an active plan to eliminate CLABSIs.

Setting

The guidelines were designed for healthcare personnel operating in acute care during a pandemic. These acute care settings include intensive care units and medical-surgical units. The organizational setting where the stakeholders currently work was a 900-bed hospital-based facility in an urban metropolis in Texas. The intensive care units comprise neuro, cardiac, surgical, and medical ICUs. The medical staff includes nurses, nurse practitioners, residents, and physicians.

Measurements and Analysis

The measurement tools for implementing the practice guidelines included the Johns Hopkins Hospital/ Johns Hopkins University (2017) level of evidence hierarchy and a rating scale from one to four. The project leader developed written guidelines (Appendix D) for the stakeholders who evaluated the graded proposed CLABSI recommendations. The stakeholder used the scale which denotes one as 'Poor,' two as 'Fair,' three as 'Good,' and four as 'Excellent.' The statistician provided support for assuring reliability or validity when analyzing the result on this tool or the databases. However, project results are considered valid because the tool answered the PICOTS question.

Procedure (Intervention)

The practice guidelines for CLABSI and the new recommended guideline during a pandemic were utilized. Three dashboards were created. (Table 1, 2, & 3).

The project team is comprised of the project lead, stakeholders (doctors, residents, and nurses), the leadership team for the acute care setting, and the administrators. The project lead's responsibilities included organizing the project timeline, liaising with the librarian to collect 50-100 articles, reviewing the articles, and grading the articles. The project leader graded the literature, wrote the recommendations then provided them to the stakeholders for rating the project lead recommendations. The stakeholder's role was to rate the recommendation written by the lead. The project lead created three dashboards.

The first dashboard lists the reviewed articles by the project leader. The articles were graded using a scale of one to four. One represents the lowest grade, indicating poor quality, while four represents the highest grade, indicating excellent quality. The data collection includes reading and grading the literature to be put in an evidence table (Table 1).

The second dashboard featured the recommendations categorized using the hierarchy of evidence levels. The grades were divided into three categories. The first grade constitutes systematic reviews and randomized control trials, graded as A, the highest value. The second tier of recommendations is the correlational and comparative studies, denoted as B, and the third grade, C, represents descriptive studies and expert opinions. Writing the recommendations and grading the recommendations (Table 2).

The third dashboard presents the stakeholders' ratings of the recommendations. The stakeholders rated them on a scale of one to four, with one being 'Poor' and four being 'Excellent' (Table 3).

The measurement tools for implementing the practice guidelines included the Johns Hopkins /Johns Hopkins University (2017) level of evidence hierarchy (Appendix F) and a rating scale from one to four. The project leader and stakeholders use the scale, which denotes one as 'Poor,' two as 'Fair,' three as 'Good,' and four as 'Excellent.' The statistician determined statistical reliability or validity when analyzing the result on this tool or the databases. However, it was considered valid because the tool answered the PICOTS question.

Statistical Analysis

The data was analyzed using SPSS version 29 software by the statistician (Fig 1). The results were evaluated using a Nonparametric test and Friedman's two-way analysis of rank variances. The statistician displayed a graphical chart of the stakeholders' ratings and project leader recommendations for the result (Fig 2). The chi-square value was used to determine the significance level (Fig 3). The statistician assisting with the project study is Dr. Kao—a statistician at the University of Texas, Arlington.

Ethics Considerations

The Graduate Nursing Review Committee (GNRC), authorized by the University of Texas Internal Review Board (IRB), determines if a project has any ethical violations. The project proposal was approved, Human Subjects Protection Training (HSP) was completed (Appendix I). In compliance with ethical guidelines, the project leader reported no conflict of interest associated with the project.

Results

Project Outcomes

The project lead adapted the results of the stakeholders' ratings with the fourteen guideline recommendations (Figure 1). The results indicated that the majority highly supported the recommendations, with a score of four representing good grades, except for stakeholders five and seven, with a score grade of one representing poor. The stakeholder five and seven are both physician and physician assistant, the recommendation rated is not within the scope of their profession which is probably the reason they rated so low. The project lead recommendation for the ninth guideline was that the unit charge nurse is responsible for ensuring all staff comply with central line standards. It was rated as two and represented fair.

There was a score grade of two for recommendations eleven and thirteen; these are the recommendations added by the project lead for pandemic situations. For recommendation eleven, the project lead discussed a plan for adequate isolation rooms for pandemic situations, possibly the reason stakeholder three graded with a score grade of two, which represents weakness; the stakeholder did not project the possibility of creating more isolation rooms for the pandemic situation only. The same third stakeholder rated the recommendation thirteen, an adequate plan for visitation policy in readiness for a pandemic, with a score grade of two. Still, the recommendation could have been better. It is possible to use the stakeholder way of rating; this is one of the study's limitations because each individual is graded differently based on their judgment and perception.

The statistician used SPSS software to evaluate the stakeholders result, and the project leader's recommendation using Friedman's Two-way analysis of variance. The pairwise comparison allows the comparison ratings of any two recommendations. The pairwise

comparison result indicates that none of the comparisons reached a p < .05. With X2(13) = 7.313, the statistician determined the significance level of p = .885, which indicated the differences among the stakeholders' ratings of the fourteen recommendations were insignificant (Fig 3).

Figure 2 contains panel of each of the 14 recommendations plotted against the 11 stakeholders' ratings (Figure 2A through M). Panels A and N show the stakeholders' unanimous grade four for the specific recommendations have the fields filled with a single wide bar. The remaining panels have unequal bars demonstrating the different number of stakeholders' level of support for each recommendation. Stakeholder two scored all the recommendations as four except recommendation two. Considering the bar chart results based on the rated grade of the stakeholders affects the shape of the bar graph bar graph.

Discussion

All recommendations have received similar responses and high score grades from the stakeholders except for one or two recommendations with low grades rated by the stakeholders. The statistical analysis of the result also indicates that the P value is < .05, a less significant value. The interpretation implies that the guidelines recommendations eleven to fourteen, as stated by the project lead for preparedness, are appropriate for use during a pandemic. The result of the project study applies to the patient. The standard guideline recommendation, the use of chlorhexidine wipes for bathing and cleaning the catheter sites, was highly scored with all grades of four, and the statistical value indicates a statistical P value of < .05 indicates the compliance of the healthcare personnel to these guidelines, infection rate will decrease among the patient population with central venous catheters.

The project's product, a guideline that reduces concurrent infections, rates will be continued because local and regional disease outbreaks to worldwide pandemics will continue to erupt. Use of appropriate guidelines will stabilize and reduce mortality related to increased infectious rates. The guideline development should continue to be modified to achieve greater success. Improved guidelines that will minimize infections during a pandemic must be encouraged.

Summary

Key Findings

The strength of the project study is that the stakeholders worked at different healthcare levels. The stakeholders are physicians, residents, physician assistants, nurse practitioners, and registered nurses. This diversity eliminated occupational bias and promoted good generalizability of the resulting recommendations guidelines. Having 11individuals rate 14 guideline recommendations reduced information bias. The project and its results will move forward toward dissemination and utilization. No other problems or gaps were discovered during the course of project.

The future implications of the project underscored the need for adequate preparedness respond to a pandemic. The leadership and the administrative of each healthcare institution should recognize the standard guidelines and this newly created guideline should be implemented during disease outbreaks. The guideline recommendations should be added to the standard guidelines for CLABSI, as cited by the Agency for Healthcare Research and Quality (2018b), and implemented for use, as an improvement in preparedness for pandemics and the reduction of infectious diseases.

Limitation

The project was limited by its eight weeks duration; the project lead needed an extension to collect more articles and invite more stakeholders, which may have contributed to variance in grading of the recommendations by the stakeholders. It may also have resulted in added bias and impacted the generalizability of stakeholders' responses.

The project's weaknesses included the number of the stakeholders' and their professional roles; the number and ratio of registered nurse, nurse practitioner, physician assistants, resident, physician participants might affect the assigned grades and limit the generalizability of the overall results. However, these professionals were impacted by COVID-19 pandemic's effect on staffing and resulted in a shortage of staff nurses due to burnout, especially nurses with many years of experience. The healthcare personnel's continued compliance with the training and sterile technique of central venous insertion could improve productivity.

The threats or difficulties limiting the implementation of the project include non-compliance of healthcare workers. The rates of CLABSI after COVID-19 were not specified in most literature. It indicates that many research studies need to be emphasized.

Conclusion

The project lead confirmed a modification needed to improve the standard of care during a pandemic. It also supported other reported studies on CLABSI guidelines by different authors. A CLABSI guideline is vital for limiting the infection rate in a healthcare institution during a pandemic. An increased infection rate in a healthcare institution during a pandemic will complicate care and impacts patients and providers in at least three significant areas: First, there is an increase in the mortality rate of patients. Secondly, there are extended long stays for hospitalized patients resulting in lack of space and admission delays for other emergent situations. Thirdly, there is an increase in the cost of care.

This project focused on developing guidelines to limit mortality rates and complications associated with HAIs from infected CVCs. The focus guidelines can promote healthcare personnel's awareness of compliance with the CLABSI guidelines, the providers ability to assist in limiting HAIs, and contribute to improving healthcare outcomes for the patients. Further reasons for the project and the guidelines that result is that healthcare institutions leadership and administrators, and government officials should be prepared for another pandemic. Even considerations of minor resources like PPEs which was lacking during the early part of the last pandemic, COVID-19, remind us that preparedness needed for impending epidemics and pandemics.

This project, the development of a CLABSI guideline for healthcare personnel during pandemic, can be utilized during health care crises such as a pandemic in all healthcare institutions. It can also provide a base for others engaged in related healthcare efforts related to emergency preparedness and CLABSI HAIs.

| 8 CINAHL The impact of central line insertion and maintenance care checklist on central line-associated bloodstream infections (CLABSI): A literature review (Gamvroulli et al., 2020). | Aim: To determine the effect of central line insertion and maintenance care checklists on CLABSI in neonatal intensive care units (NICU), Pediatric intensive care units (PICUs), and hematology/On cology units. | Method: A study was conducted from the PubMed database. 11 studies were conducted, of which seven referred to NICU, two to PICU, and two to Hematology /oncology units using a maintenance checklist for CLABSI guideline | Results: The finding indicated CLABSI was reduced in all the 11 studies, with 92% of CLABSI reduction, 50% from PICU, 28% from Hematology/ oncology units, and 64% in NICU. | Limitation: The author did not indicate the period of collection. The number of the participants ICU involved are relatively small. There is bias of population study, | Level 1: Systematic review. Rate: Weak The article was rated as weak, the period of collection for the study was not included in the study, and the population size for the study needed to be more significant. The article's discussion should have included the strengths and limitations of the study. | 2 |

| 14. CINAHL Harnessing implementatio n science to optimize harm prevention in critically ill children: A pilot study of bedside nurse CLABSI bundle performance in the pediatric intensive care unit (Woods- Hill et al., 2020). | Aim: To optimize harm prevention in critically ill children in the pediatric intensive care unit using a pilot study of bedside nurse CLABSI bundle performance. | Method: A single center cross-sectional electronic survey of 226 (71%) PICU bedside nurses were participants. A phrase COM-B (capability, opportunity, motivation) and TDF (theoretical domains framework) and behavioral models were used to explore CLABSI bundle performance and identify barrier factors to compliance. | The study indicated 160 survey questionnaire s were analyzed from 226 nurse participants. Using the COM-B model for analysis: CLABSI knowledge by the nurses were strong at 88.5% (capability). Challenges related to opportunity:3 2% of the nurses describe CLABSI bundle as stressful. 75% of the nurses reported they are motivated by the physician's attitude towards the CLABSI | Limitation. A single center for the study limits the generalizabi lity. The survey items for the study were not validated using psychometri c tests and the themes for the qualitative analysis was not specified. | Level II Correlational studies. Rate: Good Using the COM-B model for the study discovered the non - compliance indicators for the pediatric nurses. | |

| 23. CINAHL Compliance with international prevention guidelines for central line associated bloodstream infections in neonatal intensive care units in Belgium: A national survey (Mahieu et al., 2022) | Aim: To assess for adherence to international prevention guidelines for CLABSI in NICU in Belgium and to study unit compliance to CLABSI | Method: A survey was used to determine the adherence of all the NICUs that are participant for the CLABSI guidelines: These includes catheter insertion, catheter maintenance, and quality control measurement s Statistically multivariable linear regression was used to determine compliance to guideline, | Results: The overall results were 8.48/1000 central line days. CLABSI was found to be higher in larger NICU:10.87 %vs 6.69%. Compliance was highest for catheter insertion 64% but lower for catheter maintenance 47% and quality control measurement s 50%. | Limitation: There was bias in the study, the author did not specify the number of NICU hospitals that are participants and the location either in the urban or rural. Generalizati on variables were not included. The number of catheter insertion, the rounding team how many times they did the measure for the results obtained. | Level II, Randomized Control Trial Rate: Moderate compliance to prevention guideline is associated to decrease CLABSI rate. | 3 |

| 25. CINAHL Multidisciplin ary efforts lead to CLABSI reduction (Klamka, 2023). | Aim: To focus on the in-depth needs of nurse managers through an in-depth environment of learning. | Method: The study was carried out at an urban free standing children hospital, the cardiac care unit (CCU) a 44-bed unit that cares for neonates and pediatric patients with congenital and acquired heart disease and adults with acquired heart disease. CCU leaders implemented multidiscipli nary approach including intervention such as central line rounds, collaboration | Results: The focus was to decrease the infection rate from 1.64 to 0.75 over a 12-month period. The CCU was unable to achieve this goal but was able to decrease CLABSI infection to 1.05. After the 12-month period was able to achieve 100 days of CLABSI due to the continuity of the training and the intervention that was included. | Strength: The study was able to achieve positive result of decrease CLABSI from 1.65 to 1.05 even though the goal of 0.75 was not achieved. | Level: II Randomized Control Trial Rate: Good. The author of the article stated consistency for the time rounds for maintenance bundle and collaboration with IPC assist to buttress infection prevention. | 3 |

| | | with infection prevention control (IPC) and use of maintenance bundle. | | | | |
|--|---|---|--|--|--|---|
| 26. CINAHL CLABSI rounding team: A collaborative approach to prevention (Pate et al., 2022). | Aim: To identify the effect of collaborative rounding team on the reduction of CLABSI | Method: The study was conducted in an 874-bed level 1 trauma at Academic Medical Center in Charlotte, North Carolina. A collaborative team approach of nursing leaders performs audits to assess the performance of individual units in the hospital and provide education tools as needed for intervention in each unit. | Result: There was a reduction in CLABSI, except for two peaks in CLABSI rate, due to an increase in Covid-19 hospitalizatio n and a decrease in audits | Strength: The results of the study, using a collaboratio n approach compliance with the guidelines for CLABSI reduction. | Level II Randomized Control trial. Rate: Good. The author was precise with the study. | 3 |

| 28. Medline Reducing central line associated bloodstream infection (CLABSI) rates with cognitive science- based training (Lowery et al., 2022). | Aim: To determine the impact of cognitive science based CLABSI prevention training module among 541 registered nurses in different units in the Mountain West region of the United States of America. | Method: The participants were handed one CLABSI prevention bundle. Each bundle consists of 27 learning objectives to learn. | Result: The pre-training period consists of 6,642-line days. 9 CLABSI at a rate of 1.36 per 1000-line days. Post-training consists of 7,180-line days. Two CLABSI were discovered at a rate of 0.28 per 1000-line days. It corresponds to a 79% reduction in the CLABSI rate. | Limitation: The author should have discussed the study's limitations in the article. Limitation was not discussed in the article. | Level II: Randomized Control Trial Rate: Good The authors recommendati on complies with the guidelines for the CLABSI bundle. | 1 |

| | | Negative binomial regression was used to determine the impact of the hospital type and central line audit rate and a safety culture program was adopted for the association between bundle compliance and CLABSI rates. | (-0.35, P< 0.001) | | | |
|---|--|--|--|--|---|---|
| 48. CINAHL Chlorhexidine gluconate locking device for central line infection prevention in intensive care unit patients: A multi-unit, pilot randomized controlled trial (Pook et al., 2022). | Aim: To assess the use of chlorhexidine gluconate as a locking device for central line infection prevention. | Method: Participants for the study were randomized to standard care or with chlorhexidin e gluconate lock solution (CHGLS) within 72 hours after being admitted to ICU. The CHG solution was instilled into the catheter device and not infused. | Results: From the study 3, 848 patients were screened and 122 were eligible for the study. Consent was obtained from 82% of the patients. Each group comprised fifty participants, and tracking logs indicate the CHGLS was used 408 times per protocol. The | Strength: The number of participants screened for the study was 3,848 and only 122 were eligible, indicating that covariates that could cause bias in the study were already eliminated. | Level II Randomized control trial Rate: Good The positive result of the study complies with the CLABSI guidelines principles to control CLABSI infection. | 2 |

| 60. Medline Compliance with Central line maintenance bundle and infection rates (Tripathi et al., 2023) | Aim: To identify the correlation between reported CLABSI compliance and CLABSI rate as a solution for patient safety network. | Method: The study was from January 11 to December 21 in a 159-bed hospital. Data on bundle compliance were examined in correlation with the CLABSI rate per month. Negative binomial regression was used for analysis to determine the impact of hospital type and central line audit rate. | Results: The hospital reported CLABSI during the study was 27 196 on 20 274 565-line days (1.34 CLABSI/100 0-line days). The observed rate of bundle opportunities is 2 460 133, out of which 2 085 700 were compliant. There was a negative correlation between monthly bundle reliability for reported CLABSI bundle compliant and observed. | Strength: 159 hospitals are large enough for general variability. Limitation: The unit of the hospital, number of patents as participants and the site of the catheter were not listed as confound variables for the study. | Level I Randomized control trial. Rate: Good The result of the study is compliant to evidenced- based study. Adherence to practice guidelines will result to CLABSI reduction. | 4 |

| Decreasing central line associated bloodstream infection through limiting the use of central venous catheters for routine blood draws (Kuriakose, 2020) | Aim: To evaluate the rate of CLABSI with central line venous catheter constantly used for blood draws. | Method: The nursing staff were educated on limiting the use of central lines for blood draws. A pre- and post-education study was used to determine the CLABSI rate, and measurable outcome were compared. | Results: The number of Central venous catheters accessed for blood draws decreased. Decrease CLABSI event rate. | Strength: The result of the study supports CLABSI guidelines to limit CLABSI rate of infection. Recommen dation: The use of central line catheter use for blood work should be limited. Since the results of the study indicated that limiting the number of times the central lines are accessed for blood draws reduced CLABSI. | Level II Randomized Control Trial Rate: Good The focus of the study is limiting CLABSI rate according to guidelines principles. That is a good and reasonable conclusion. | 4 |

| implementation model to reduce central line associated bloodstream infections (Azar et al., 2019). | agile implementation model to reduce CLABSI | using an observationa l study in a tertiary care hospital in Indianapolis from January 2015 to June 2017 | reduced the CLABSI from 1.76 to 1.24. Rate ratio=0.70, P=0.011. Clostridium difficle and surgical site infections were also observed to be reduced. | the study, the number of central line catheters, and central line days should have been discussed during the study. These confounded variables affect the generalizati on and cause bias in the study. | Rate: Weak The article needed to be more detailed. The central line days, the number of catheters observed, and what the agile implementatio n model entails need to be further explained. | |
|---|---|--|--|--|--|---|
| 65. Medline Prolonged use of intravenous administration sets on central line-associated bloodstream infection, nursing workload and material use: A before-after study (Van de Pol et al., 2023). | Aim: To evaluate the impact of prolonged intravenous administration sets from four to seven days on the incidence of CLABSI | Method: A retrospective study was used for a single tertiary care hospital. St Antonius hospital Nieuwegein, in Netherlands. It is a 32-bed ICU that offers both medical and surgical care for patients above the age of 18. The study included pre and post-intervention. | Results: The number of CLABSI rates did not change despite the changes in the time interval from four to seven days. Recommend ation The prolonged use of IV administratio n sets is safe for up to seven days, as in the case of 96 hours. | Limitation: The study did not indicate the severity of the illness of the patient to determine if the CVC insertion was done in an emergency for slight chances of infection | Level II Retrospective study. Rate: Good The article meets up with the requirement for human research and the contents of the article: Abstract, Aim/objective , method results discussion, and conclusion. Limitation of the project | 4 |

| 68. PubMed Trends of central line- associated bloodstream infections in the intensive care unit in the kingdom of Bahrain: Four years' experience (Al-Khawaja et al., 2021). | Aim: To evaluate the trends of the rates of CLABSI over four years, the risk factors, etiology, and the antimicrobial susceptibility of the isolated pathogens. | Method: The study design was a prospective case-control. The study followed CDC surveillance methods for CLABSI in the intensive care unit. The implemented prevention bundle was audited. | Results: During the study, thirty-four CLABSIs were identified. With the implemented prevention bundle, there is a significant CLABSI reduction from 4.7/1000 central line days in 2016 to 1.4/1000 central line days by 2018. Recommend ation: Implementin g a prevention bundle at | Strength: The study achieved a positive result of CLABSI reduction. Limitation: The study was conducted at a single center, so the results of the study cannot be generalizabl e to other private or public settings. The critical condition of the patient used for the study was not indicated. | Level II Prospective Case control study. Rate: Good The article is well presented had all the information details. | 2 |

Appendix E

Recommended Guideline for Stakeholders Grading

The survey includes recommendations that have been written according to the literature in CLABSI during and after pandemic. Please rate each recommendation on a scale of 1-4.

1-Poor, 2-weak, 3-Moderate, and 4-Good.

A link to share folder where you will find all the literatures that was used to write the recommendations as well as the evidence table is at the link. You are welcome to view them but not required to view them.

Recommendation 1. Only credentialed healthcare providers may insert central venous catheters (AHRQ, 2018).

Recommendation 2. Full PPE and aseptic technique is required for catheter insertion (Afonso, et al., 2016).

Recommendation 3. Hand hygiene with soap and water should be done before and after procedure (Myatra, 2019).

Recommendation 4. The central venous catheter site dressing must be changed every seven days or as needed when contaminated (Gamvroulli et al., 2020).

Recommendation 5. The lumen (s) of the central venous catheter must be cleansed daily with chlorhexidine wipes, and the needless connectors covered with curo caps (Gillis et al., 2023).

Recommendation 6. The staff nurse must assess the central venous catheter site at the beginning of each shift for signs of infection (Hecht, et al., 2020)

Recommendation 7. Intravenous tubing changes per guidelines. Primary line changes every 96 hours, secondary and parenteral nutrition line (TPN) every 24 hours, and the lipid line changes every 12 hours (Van de pol et al., 2023).

Recommendation 8. All staff nurses including agency nurse must receive education and skill check off on central line care. Permanent staff will check off annually (Aloush et al., 2018). Recommendation 9. The unit charge is responsible for ensuring all staff are compliant with central line standards (Achary, et al., 2019)

Recommendation 10. Patients with central venous catheters must be bathed daily with 2 % chlorhexidine wipes (Lin et al., 2017).

Recommendation Eleven. Plan for adequate isolation rooms, either existing rooms or those that may be adapted in preparation for a pandemic (Sharma et al., 2020).

Recommendation Twelve. Plan for an adequate supply of personal protective equipment (PPE) in preparedness for the pandemic. The supply chain manager and chief operational and finance officer manager make a budget for the purchase of extra-large supplies of PPE (Haegdorens et al., 2022).

Recommendation Thirteen. Plan for visitation policy in readiness for a pandemic—the infection control manager and administration effect restriction policy (Jaswaney et al., 2022).

Recommendation Fourteen: Plan to decontaminate surfaces such as overhead tables, doorknobs, and nursing stations to minimize infection rate. The environmental service manager and the supervisor ensure that environmental staff members do thorough and constant cleaning (Cutts et al., 2021).

Appendix F
Screening Tool: Evidence Level Hierarchy

| Evidence Levels | Quality Ratings |
|--|---|
| Systematic reviews of randomized control | A – High quality. Consistent, generalize results, consistent recommendation based |
| trial with or without meta-analysis. | upon literature review that is evidence-based practice. |
| Correlational studies | B – Good quality. Equitably consistent |
| | results, reasonably consistent |
| | recommendations based on comprehensive |
| | literature reviews. |
| Expert/Opinion studies | C – Low Quality. Little evidence with |
| | inconsistence results, conclusion cannot be |
| | drawn. |

GNRC Statement

| GNRC Proposal for | Abiodun Adejumobi | (student name) |
|------------------------------|-------------------------------|---------------------------|
| Student Email for GNRC Lette | er to be sent tooa | a8655@mavs.uta.edu |
| Title of Project A CLABSI | Guideline for Healthcare Pers | sonnel during a Pandemic_ |
| Faculty Instructor | Dr. Deborah Behan | |

GNRC Decision: CONDITIONS MET WITH FACULTY HELP 7-28-23

This form reflects information required on the Proposal Rubric. Faculty Instructors initial indicating criteria is met. Students submit the form with their Proposal.

| Section | Meets criteria |
|---|--|
| Provides gap in the area of population and the | Yes; |
| practice setting with supportive data (National, State, and Local). This is addressed in the introduction. If a Guideline should be created, states the need for a guideline for nurses to follow. If a database project, then states the need for data and what counties/state in which there is a need to create a scorecard. | Condition: needs to support with citations pg. 9 the complications arising from COVID-19spending to manage the outbreak. Does not clearly say pg. 9 last paragraph speaks to her local organization. It needs to say that using personal communication or provide numbers. |
| Writes the PICOTS (Population, Intervention, Comparison, Outcome, Time, Setting) | Yes P- Healthcare staff personnel: Doctors, Resident doctors, and nurses. Taking care of patients with a central line and at risk for CLABSI during a pandemic I – developing a guideline for CLABSI prevention to be used by healthcare personnel during a pandemic C- Comparison with the efficacy of guidelines typically used during non-pandemic time periods O- Evaluation of literature, writing of recommendations, grading of recommendations, and rating of recommendations by stakeholders T- 8 weeks S- Acute care setting |
| Review of Literature (ROL) The intervention's specific evidence is discussed from three different disciplines. The evidence table is in the appendix; For a guideline project the ROL focuses on the topic and the grading of literature to solve the problem/gap. If a database project the ROL focuses on the topic of the database that is needed to create a scorecard. Correctly identifies project as QI, EBP, Guideline, or Database Quality Improvement change in process, Evidence-Based change in practice, a Guideline with a specific format that | Yes |

| 211 6 11 14 4 4 21 22 2 2 2 2 | |
|---|-----|
| will be followed to create the guideline, or a database | |
| project that states where and how the data will be used. | |
| Uses appropriate framework for the type of project. Example: | yes |
| QI – PDSA or equivalent EBP – IOWA, John Hopkins, Stettler, or equivalent | |
| Guideline – AHRQ Clinical Practice Guidelines | |
| Database- SDOH model (Health People 2030) | |
| Correctly constructs a project question to | Yes |
| include: 1. Patient population | |
| 2. Intervention or change | |
| 3. Specific and measurable outcome | |
| 4. Time5. Setting | |
| Example for Guideline: Does a guideline on xx that is | |
| developed in response to an identified need and supported by critically appraised published literature | |
| and reviewed and graded by stakeholders result in | |
| recommendations for implementation? | |
| Example for Database: For xx population will patterns and trends identified in large data on xx to create a | |
| scorecard that will guide to best interventions to | |
| improve quality and safety of the patient population in the identified public use data file (PUDF) within xx | |
| (state)? | |
| Correctly constructs objectives for the project | yes |
| Action verbs are used with objectives that include each step | |
| of the plan to complete the project. | |
| | |
| | |
| Methodology includes the following: | |
| | |
| | |
| 1. Setting (should not be identifying) in detail; for | yes |
| a guideline describes the setting in which the guideline could be used (population) for a | |
| database it should be the same as for QI and EBP | |
| | |
| 2. Population (describes the population in | yes |
| relation to their project with inclusion/exclusion criteria) in detail; documents the anticipated | |
| sample size. A guideline may describe the | |
| population of stakeholders that the guideline targets as well as patients (as applicable) receiving | |
| the care from the recommendations. The database | |
| will be the same as QI and EBP | |
| 3. Role on team (no names) for all involved in | Yes |
| the project; for guideline the team is the librarian involved in searching databases and stakeholders | |
| who are involved in grading the | |
| recommendations. For a database project Dr. | |

| | 77° (1774 '111 d (d (1 | |
|-----------|---|-----------------|
| | Tietze and FA will be the team that work on review of data. | |
| | review of data. | |
| | | |
| | | |
| 4. | Education of team involved in project (is in | Yes; fix slides |
| | outline, PowerPoint, or detailed form if required | |
| | for implementation of project); for a guideline | |
| | should be about the communication with librarian | |
| | and stakeholders involved in evaluating the | |
| | recommendations; for a database the education | |
| | will be Dr. Tietze and the FA on what variables | |
| | are needed for analysis and how the scorecard is | |
| | going to be created | |
| | | |
| 5. | How the intervention or change will be | yes |
| | implemented (specifics); For a guideline the | · |
| | search strategy, detailed decisions on grading the | |
| | literature, decision on specific article use, | |
| | stakeholder interaction plan; for a database | |
| | detailed information on how the database will be | |
| | accessed and used as well as building the | |
| | scorecard for red, yellow, and green and what | |
| | percentages are to be met for each. | |
| | | |
| 6. | Exact data to be collected; the process of | yes |
| | data collection, instrument used for data | • |
| | collection; for a guideline would include | |
| | stakeholder opinion and the scale of 1-4 to rate | |
| | recommendations, expert opinion decisions on | |
| | what is included, how decisions will be made | |
| | regarding the grading of literature, grading of | |
| | recommendations. For a database the excel file of | |
| | all variables that will be collected for analysis as | |
| | well as creation of a scorecard where the range of | |
| | acceptable is identified according to the literature. | |
| 7 | D-4-9 -64b4-4'-4'14b - 11 | |
| 7. | Detail of the statistical methods and | yes |
| | ethics to be used including descriptive, and /or | |
| | inferential methods; for a guideline descriptive | |
| | stats on grading of literature, recommendations | |
| | (A,B,C), and stakeholder opinions (1-4); for | |
| | database descriptive data will be used to put into | |
| | the scorecard for determination if the range is met | |
| Doghb | for safe quality care. oard is included in appendix and has method for | Voc |
| | ifying data; Includes the master coding for de- | yes |
| | ation and the master coding values for data. | |
| | g a tool for the project, includes validity | Yes |
| | liability (references and permission in appendix); | 103 |
| | deline the NIH/AHRQ framework is used. For a | |
| | is created using the literature there is no established | |
| | y or validity, thus students must identify there is no | |
| | ned reliability; however, if the PICOTS can be | |
| | d using the tool they can say it was assessed to have | |
| | dity; for database project the reliability and validity | |
| of the PU | | |
| | | |

| APPENDICES Includes: | |
|--|---|
| If updating a current guideline , it is included in the appendices, Legend for grading of recommendations, evidence table and grading of literature | Yes; |
| Approval Letter | yes |
| If education of team or patients is part of proposal, includes the educational outline and/or PowerPoint | Yes; Condition: take dashboard out of the slide on pg. 46 and put the new one in; slide on pg. 49 change to read literature, grade literature, write recommendations, grade recommendations, ask stakeholders to rate the recommendations written by project lead |
| Dashboard for data collection; Includes every tool that will be used: screenings, | yes |
| surveys; Marketing announcement; scripts; timeline, scorecard | Yes; do not see the |
| SWOT, Risk Management, Organizational Readiness, and GANTT chart in appendix | RM nor OR |
| Monetary budget for the project and if receiving a grant or scholarship | yes |
| Verification of UTA Protecting Human Research Participants Training | yes |

University of Texas at Arlington College of Nursing and Health Innovation Student Project Review Application

Student Name: Abiodun Adejumobi

N6333 Professor Name: Dr Deborah Behan

Project Title: A CLABSI Guideline for Healthcare Personnel during a Pandemic

Project Type: Please select the appropriate Project Type (Refer to definitions at the end of this document):

| Quality Improvement Project |
|-----------------------------|
| Evidence-based project |
| x-Guideline project |

Description of Project: Follow the GNRC DNP Proposal Rubric to make sure the proposal is complete for submission

Please note: If you have received a grant, you must complete the financial form from the university http://www.uta.edu/fao/apply/forms.php

Project starting semester date (DNP Practicum I start date): August 22nd, 2023

Project expected completion Date (DNP Practicum II end date): March 2024.

The checklist below will assist you to determine whether a project requires review for approval only at the Graduate Nursing Review Committee level or also at the UTA Institutional Review Board (IRB). **Note: A GNRC member will review all projects as a first step in the full review process.**

Preliminary Questions:

| 1. | Is the propo | sed p | roject a guideline? |
|----|--------------|-------|---------------------|
| | x Yes | or | No |

If you answer "no" to the question, continue with the secondary checklist.

| | Decision Checklist | False | True |
|---|---|-------|------|
| 1 | The purpose of the project is to describe standard care, determine best practice | | |
| | based upon the evidence or improve internal (local agency) processes, practices, | | |
| | costs, or productivity. | | |
| 2 | You are measuring an existing practice that may or may not have been shown | | |
| | effective in the literature. | | |
| 3 | There are no risks to human subjects such as disclosure of protected health | | |
| | information or risks from changes in usual care delivery. | | |
| 4 | You will use a small sample size data set but large enough to observe the purpose | | |
| | of the project. There is no need for a power analysis to determine a sample size. | | |

| 5 | There will be no participants data used outside your setting because another | |
|---|--|--|
| | setting may not provide care the same way. | |
| 6 | The project will NOT be described as research in public presentations, | |
| | portfolios, or other representations and it is not generalizable. | |
| 7 | There is NO withholding of any aspect of a standard of care or NO testing of an | |
| | intervention that is not standard of care (neither consensus-based or evidence- | |
| | based.) | |
| 8 | The project DOES NOT involve grant/contract funding or sponsorship for a | |
| | research study that requires IRB approval? | |
| | research stady that requires into approvar. | |
| 9 | The project DOES NOT involve a drug or device used outside of usual medical | |
| 9 | | |
| 9 | The project DOES NOT involve a drug or device used outside of usual medical | |
| 9 | The project DOES NOT involve a drug or device used outside of usual medical practice, including non-FDA approved agents or the use of any off-label uses of | |

If you answer *False* to **ANY** of the questions above, a review at all levels may be necessary (i.e. the department level and the university level.) You must complete this checklist, sign it and submit it to the GNRC with the **UTA university level IRB protocol document).** If determined necessary to go to the UTA IRB, then final approval of your project will come from the UTA (university level) IRB. If an animal is involved, then the university IRB for animal involvement will review.

If you answer *True* to **ALL** of the above questions, you must complete this checklist, sign it and submit it to the GNRC. Final approval for your project will come from GNRC.

In general, Quality Improvement and Evidence-based projects and Guidelines are NOT considered human subjects' research.

According to 45 CFR 46.102(d) research is defined as "a systematic investigation, including research development, testing and evaluation, designed to develop or contribute to generalizable knowledge."

** Student attestation: In signing below, I confirm that I have reviewed this application form with my N6333 Professor, and he/she is in full agreement with the form as submitted**

I have reviewed the decision checklist and believe my answers to represent the project titled above.

| Student signature: Abiodun Adejumobi. | Date: 07/02/2023 | |
|--|--------------------------|-----------------------------|
| I have reviewed this form with the student | and the answers represen | t the project titled above. |

DEFINITIONS FOR USE WITH GNRC DNP PROPOSAL

Evidence Based Project (EBP):

Guideline Development: The process of developing evidence-based statements which assist providers, recipients, and other stakeholders to make decisions about appropriate health interventions (World Health Organization, 2003).

Implementation Project: A project consisting of a specified set of activities designed to put into practice an activity or program of known dimensions that currently is not being used within the single entity (i.e. patient care unit, clinic, or service area). (National Implementation Research Network, 2014).

Quality Improvement Project (QI):

A project designed to evaluate changes that will lead to better patient outcomes (health), better system performance (care), and better professional development (Quality and Safety in Healthcare, 2007) within a single entity (i.e. patient care unit, clinic, service area). Outcomes are not **generalizable** beyond the single entity. (This may be a screening tool, educational intervention, or change in procedure)

EBP/QI Project:

A combination of implementation with guideline development or implementation project, then evaluating the changes as a Quality Improvement Project overtime.

Guideline Project:

Statements that include recommendations intended to optimize patient care informed by the literature (IOM, 2011, p.15)

Appendix H

Script for Training About the Project Study

The introduction of my topic: A CLABSI Guideline for Healthcare Personnel during a Pandemic. CLABSI is one of the significant causes of hospital-acquired infections (HAI)). It must be considered a considerable factor in infections in healthcare organizations, especially during the Pandemic. If the rate increases and adequate care is not taken, it becomes compromised, which could lead to increased mortality (Alotaibi et al., 2023). During the last Pandemic, the number of individuals affected in America with COVID-19 was 192,775,054 (WHO, 2023). In the last quarter of 2020, the CLABSI rate overall US was 47% (CDC, 2020). This is one of the reasons why I was fascinated with using CLABSI for the project study.

Central line-associated bloodstream infections (CLABSI) will be limited in the healthcare organization and during the Pandemic if the healthcare organizations policy for CLABI is followed by healthcare personnel because the guidelines are modified to observe the standard guidelines of the Agency for Healthcare Research and Quality (AHRQ2018). This is one of the essentials of my project, using evidence-based literature reviews to develop recommendations that would be implemented to the standard guidelines of AHRQ for use as a guideline during the Pandemic.

For the study, the project lead reviewed seventy-four literature articles and developed fourteen recommendations, ten basic standard guidelines as written by AHRQ, 2018, and four new recommendations. The project lead first graded the fourteen recommendations using the evidence level of hierarchy. The project lead sent the recommendations to the stakeholders for grading. The statistician analyzed the results of the grading and the project lead

recommendations statistically. The analysis result identified that the stakeholders graded the new recommendations with a high score, indicating the P value < .05. Statistically, indifference explains that the leadership of healthcare organizations can implement the recommendations.
